

Document Loaders

Combining language models with your own text data is a powerful way to differentiate them. The first step in doing this is to load the data into “documents” – a fancy way of say some pieces of text. This module is aimed at making this easy.

A primary driver of a lot of this is the [Unstructured](#) python package. This package is a great way to transform all types of files – text, powerpoint, images, html, pdf, etc – into text data.

For detailed instructions on how to get set up with Unstructured, see installation guidelines [here](#).

The following sections of documentation are provided:

- [Key Concepts](#): A conceptual guide going over the various concepts related to loading documents.
- [How-To Guides](#): A collection of how-to guides. These highlight different types of loaders.
