Python REPL

Sometimes, for complex calculations, rather than have an LLM generate the answer directly, it can be better to have the LLM generate code to calculate the answer, and then run that code to get the answer. In order to easily do that, we provide a simple Python REPL to execute commands in. This interface will only return things that are printed - therefore, if you want to use it to calculate an answer, make sure to have it print out the answer.

Bash

It can often be useful to have an LLM generate bash commands, and then run them. A common use case for this is letting the LLM interact with your local file system. We provide an easy component to execute bash commands.

Requests Wrapper

The web contains a lot of information that LLMs do not have access to. In order to easily let LLMs interact with that information, we provide a wrapper around  [latest](#)  module that takes in a `URL` and fetches data from that `URL`.

[Skip to main content](#)

Google Search

This uses the official Google Search API to look up information on the web.

SerpAPI

This uses SerpAPI, a third party search API engine, to interact with Google Search.

Searx Search

This uses the Searx (SearxNG fork) meta search engine API to lookup information on the web. It supports 139 search engines and is easy to self-host which makes it a good choice for privacy-conscious users.
